

# Notes Python

## Bases

```
#!/usr/bin/python3

# output
print ("Hello, Python!")
print(x, end=" ") # Appends a space instead of a newline in
Python 3

# input
x = input("something:")

# raise exception
raise IOError("file error") #this is the recommended syntax
in Python 3
```

```
# Quotation in Python
word = 'word'
sentence = "This is a sentence."
paragraph = """This is a paragraph. It is
made up of multiple lines and sentences."""
```

## Variable Types

```
# Simple Assignment
counter = 100           # An integer assignment
miles   = 1000.0        # A floating point
value   = 3e+26J         # A complex
name    = "John"         # A string

# Multiple Assignment
a = b = c = 1
a, b, c = 1, 2, "john"
```

```
# deletion  
a, b, c = 1, 2, "john"
```

```
str = 'Hello World!'  
  
print (str)          # Prints complete string  
print (str[0])       # Prints first character of the string  
print (str[2:5])     # Prints characters starting from 3rd  
to 5th  
print (str[2:])      # Prints string starting from 3rd  
character  
print (str * 2)       # Prints string two times  
print (str + "TEST") # Prints concatenated string
```

```
list = [ 'abcd', 786 , 2.23, 'john', 70.2 ]  
tinylist = [123, 'john']  
  
print (list)          # Prints complete list  
print (list[0])        # Prints first element of the list  
print (list[1:3])      # Prints elements starting from 2nd  
till 3rd  
print (list[2:])        # Prints elements starting from 3rd  
element  
print (tinylist * 2)    # Prints list two times  
print (list + tinylist) # Prints concatenated lists
```

```
tuple = ( 'abcd', 786 , 2.23, 'john', 70.2 )  
tinytuple = (123, 'john')  
  
print (tuple)          # Prints complete tuple  
print (tuple[0])        # Prints first element of the tuple  
print (tuple[1:3])      # Prints elements starting from 2nd  
till 3rd  
print (tuple[2:])        # Prints elements starting from 3rd  
element  
print (tinytuple * 2)    # Prints tuple two times  
print (tuple + tinytuple) # Prints concatenated tuple
```

```
dict = {}  
dict['one'] = "This is one"  
dict[2]      = "This is two"
```

```
tinydict = {'name': 'john', 'code':6734, 'dept': 'sales'}  
  
print (dict['one'])           # Prints value for 'one' key  
print (dict[2])              # Prints value for 2 key  
print (tinydict)             # Prints complete dictionary  
print (tinydict.keys())      # Prints all the keys  
print (tinydict.values())    # Prints all the values
```

```
#Data Type Conversion  
int(x [,base]) #Converts x to an integer. The base specifies  
the base if x is a string.  
float(x) # Converts x to a floating-point number.  
complex(real [,imag]) # Creates a complex number.  
str(x) # Converts object x to a string representation.  
repr(x) # Converts object x to an expression string.  
eval(str) # Evaluates a string and returns an object.  
tuple(s) # Converts s to a tuple.  
list(s) # Converts s to a list.  
set(s) # Converts s to a set.  
dict(d) # Creates a dictionary. d must be a sequence of  
(key,value) tuples.  
frozenset(s) # Converts s to a frozen set.  
chr(x) # Converts an integer to a character.  
unichr(x) # Converts an integer to a Unicode character.  
ord(x) # Converts a single character to its integer value.  
hex(x) # Converts an integer to a hexadecimal string.  
oct(x) # Converts an integer to an octal string.
```

## Basic Operators

## Object Oriented

```
#!/usr/bin/python
```

```
class Employee:
```

```

'Common base class for all employees'
empCount = 0

def __init__(self, name, salary):
    self.name = name
    self.salary = salary
    Employee.empCount += 1

def displayCount(self):
    print "Total Employee %d" % Employee.empCount

def displayEmployee(self):
    print "Name : ", self.name, ", Salary: ", self.salary

"This would create first object of Employee class"
emp1 = Employee("Zara", 2000)
"This would create second object of Employee class"
emp2 = Employee("Manni", 5000)
emp1.displayEmployee()
emp2.displayEmployee()
print "Total Employee %d" % Employee.empCount

```

```

# Built-In Class Attributes
print "Employee.__doc__:", Employee.__doc__
print "Employee.__name__:", Employee.__name__
print "Employee.__module__:", Employee.__module__
print "Employee.__bases__:", Employee.__bases__
print "Employee.__dict__:", Employee.__dict__

```

```

# Class Inheritance
class Parent:          # define parent class
    parentAttr = 100
    def __init__(self):
        print "Calling parent constructor"

    def parentMethod(self):
        print 'Calling parent method'

    def setAttr(self, attr):
        Parent.parentAttr = attr

```

```
def getAttr(self):
    print "Parent attribute :", Parent.parentAttr

class Child(Parent): # define child class
    def __init__(self):
        print "Calling child constructor"

    def childMethod(self):
        print 'Calling child method'

c = Child()          # instance of child
c.childMethod()      # child calls its method
c.parentMethod()    # calls parent's method
c.setAttr(200)       # again call parent's method
c.getAttr()          # again call parent's method
```

```
# Overriding Methods
class Parent:          # define parent class
    def myMethod(self):
        print 'Calling parent method'

class Child(Parent): # define child class
    def myMethod(self):
        print 'Calling child method'

c = Child()          # instance of child
c.myMethod()         # child calls overridden method
```
